Abstract/Introduction

AIM

The aim of this project is to draw a 3D image of the object with the help of processing IDE and Arduino IDE. This will be achieved by the use of ultra sonic sensor and servos.
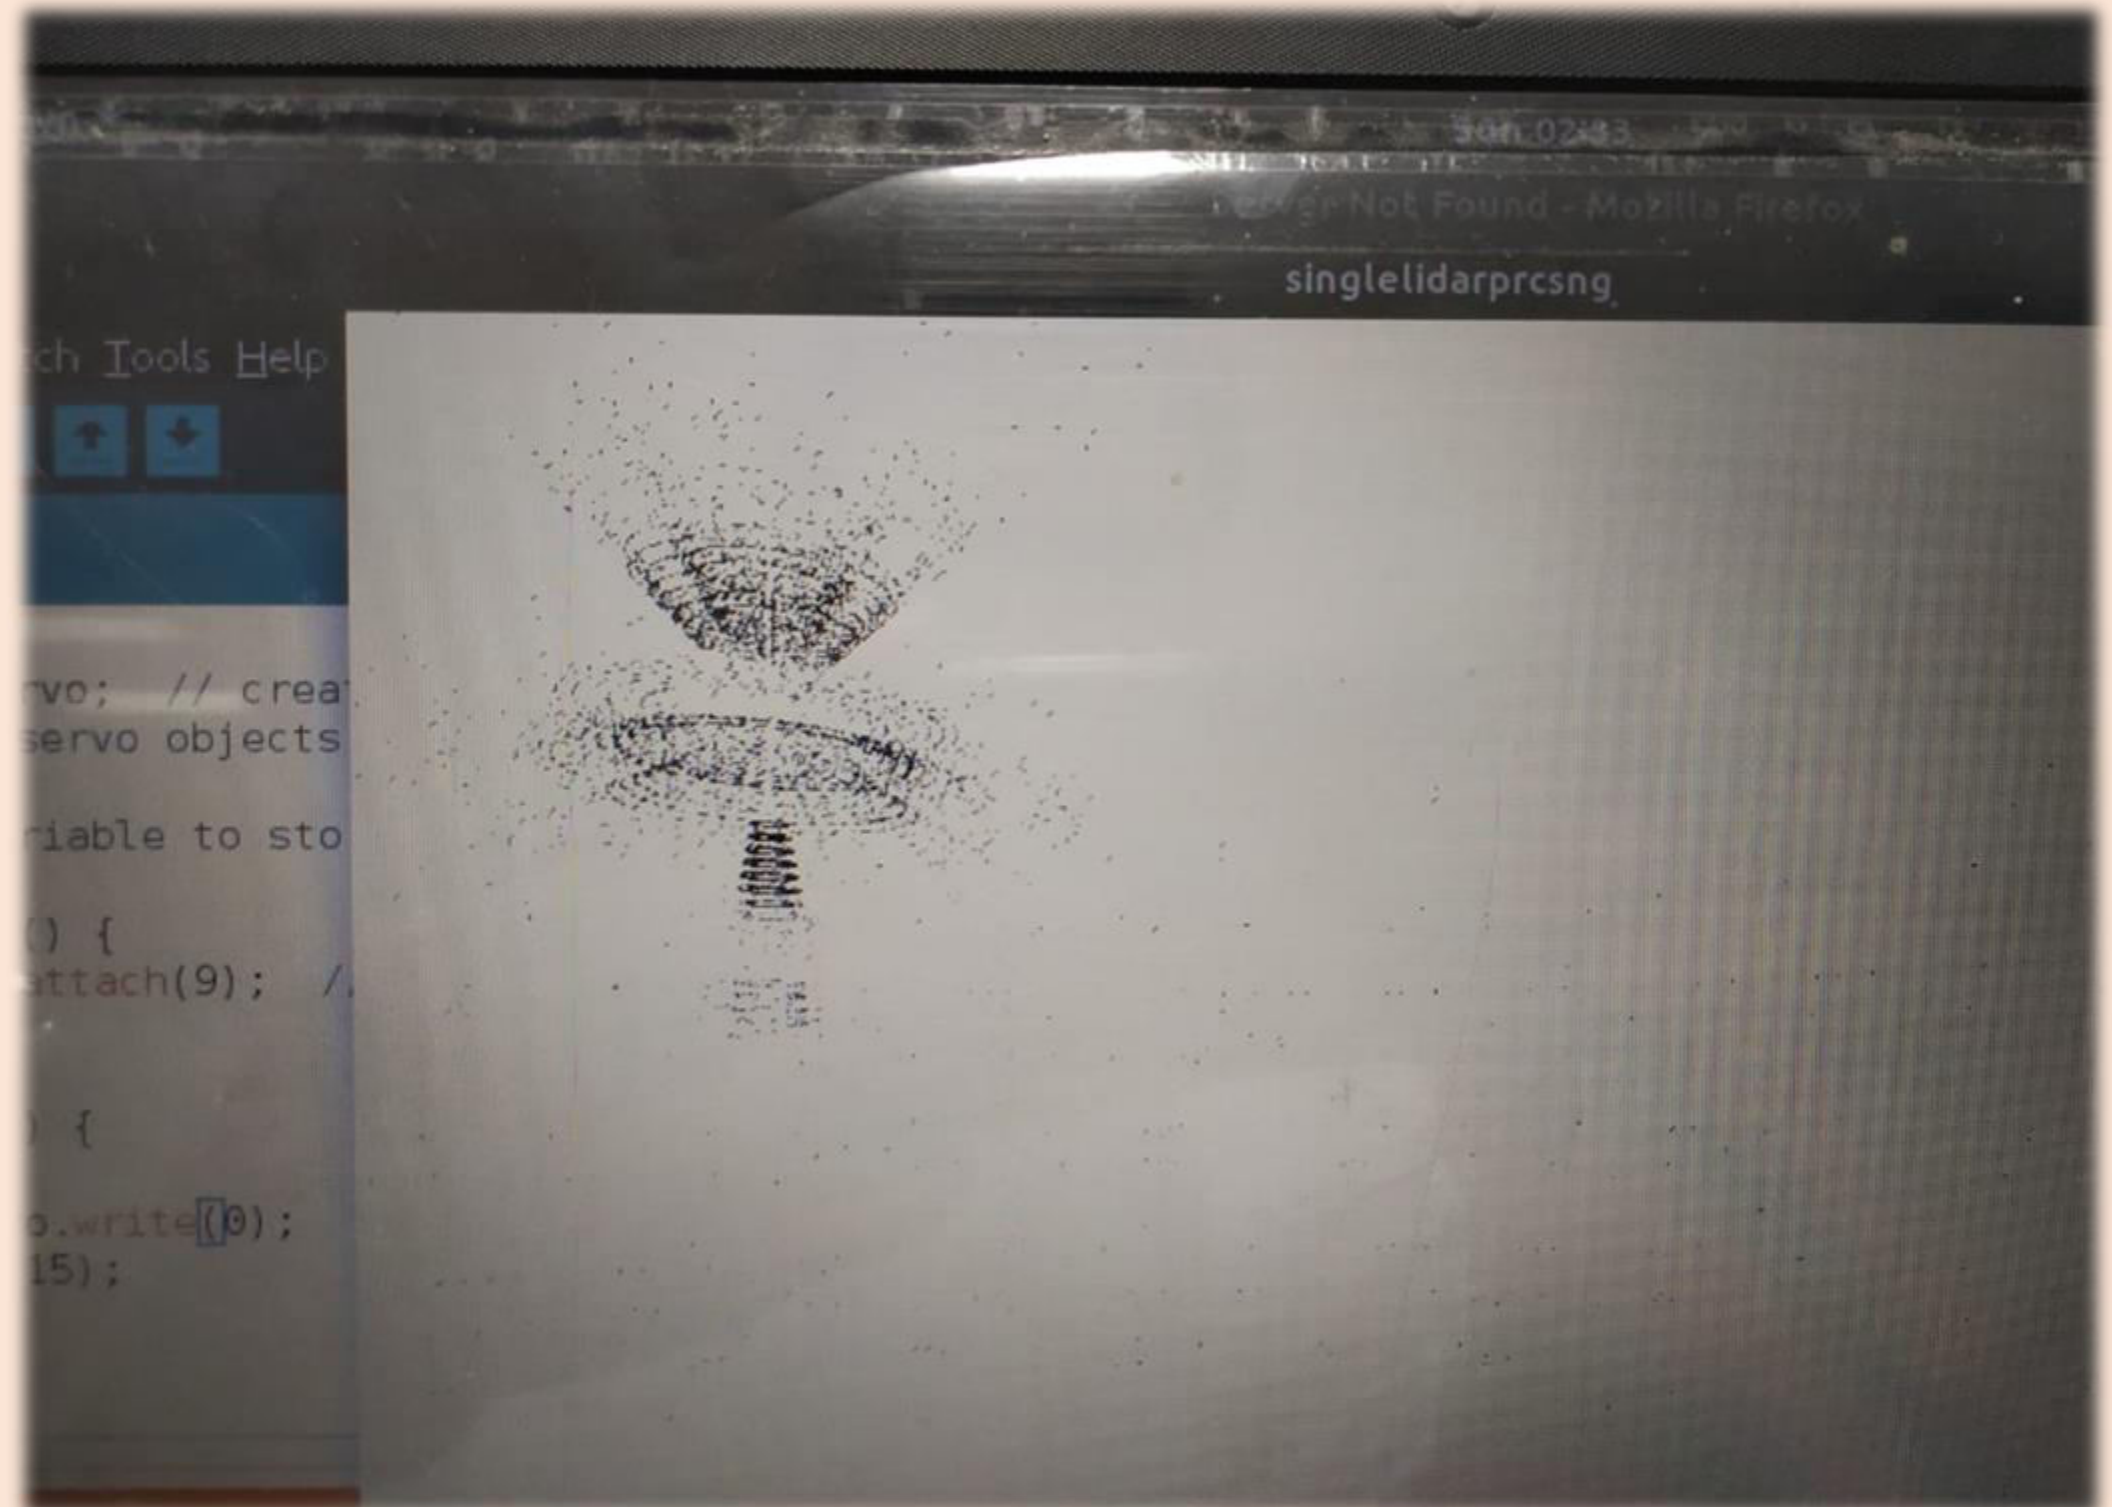

DIFFERENTIATING OBJECTS

Through this model, different objects could be identified for the particular range of distance.

Lines will be generated by 3d mapping.

Methodology

• The Project consists of two major parts:

    1.Mechanical Structure 2.Algorithm

• **Mechanical structure**

1.we have used two servos, connected to each other such that the second servo is fixed on the axis of first servo.
2.The first servo will rotate 180 degree in the horizontal plane(X-Z) and so the second servo will rotate in vertical plane(X-Y).
3.On the axis of second servo one Ultrasonic sensor is fixe.
• **Algorithm**

1.Each Ultrasonic sensor will give the distance of the object in front of it, now suppose there is a object of some height placed in front of our model then it gives distance of the point in front of the sensor , now we will rotate the second servo by some angle and then it will give the distance of point just next to last point so by continuing this thing we can map the height of the object.
2.For the width of the object we will rotate the first servo by some small angles upto 180 degrees.
3.By processing we can then map the whole object.

Results

1.Now we can map the surrounding and get a 3D view of the objects present in it.
2.Ultimately we would be able to identify the 3D view of the objects by taking multiple readings

OUTPUT

Conclusion

1.With the help of our model we can map objects.

2.This is a very low cost model Which can map the surrounding.
